1 INTRODUCTION AND BACKGROUND

1.1 Water heaters in California

Water heaters, sometimes referred to as the "forgotten appliance," account for roughly 25% of all household energy use in California, making them the second-largest single source of residential energy consumption¹, behind only space heating. Roughly 40% of US households use electricity to heat water², although the percentage is lower in California, at only 6% for single family homes and 14% for multifamily homes³. For homes that use natural gas to heat water, 49% of household gas use can be attributed to water heating⁴. For homes that use electricity, a significant portion of their electricity bill is attributed to water heating. PG&E estimates that gas water heaters are approximately 40% cheaper to operate than electric water heaters⁵.

In California, some homes and lower-income communities throughout the state, such as the San Joaquin Valley, lack access to natural gas lines; currently the most affordable way to heat water for residential use. In 2014, California's legislature passed AB 2672, which requires the California Public Utilities Commission to analyze economically feasible options that can increase access to affordable energy in disadvantaged communities. For those options that are cost-effective, the bill requires the commission to take appropriate action and determine the appropriate funding sources.⁶

Further, some of California's multi-family water heating fleet is aging and many multi-family building owners have been slow to uptake newer technologies. While classic landlord-tenant barriers may be one reason; another reason is that replacing a gas appliance triggers additional expenses. Gas appliance replacement triggers a requirement that the building pass a Combustion Appliance Zone (CAZ test). While the costs of performing the test are known, the cost of mitigating any test failures is not and can be extremely costly. For this reason, building owners are prone to have a "if it isn't broke don't fix it" mentality when considering water heater replacements.

1.2 Emerging water heating technologies

Heat pumps are gaining popularity for both space heating and cooling and water heating applications due to their high efficiency and flexibility. Heat pump water heaters are more widely available than ever before. A key feature of the heat pump water heater is that they are hybrids. They function both as a heat pump (a reverse refrigerator) during periods of low demand, and as a traditional electric resistance water heater during period of high demand. Thus, unlike incumbent technologies, the overall efficiency of heat pump water heaters is highly dependent on hot water load profiles and ambient conditions. Also, the load shape profile of heat pump water heaters in considerable different than standard electric water heaters. Overall, the market share of heat pump water heaters is still low.

Recent research has shown that to reach net-zero energy by 2050, Californians will need to run their homes, cars, and businesses off of electricity from carbon-free sources⁷. This means two things for water heaters in California:

- 1. The share of electric water heaters will increase dramatically in the coming years, and
- 2. Water heaters will be powered by intermittent energy sources like solar and wind.

Another recent study by the Brattle Group⁸ found that water heaters, specifically grid-connected water heaters, offer an attractive opportunity for improving the reliability, economics, and environmental footprint of the green-powered grid. The growing adoption of intermittent generating sources increases the value of flexible loads to system operators. Grid-enabled or grid-interactive water heaters could provide flexible load in the following ways:

- 1. Demand response (shift water heater demand to times of low system demand),
- 2. Energy storage (absorb energy in times when the marginal cost is low or negative due to the high penetration of intermittent renewables),
- 3. Frequency regulation and other grid balancing services (water heaters controlled over very short time intervals with near instantaneous response).

2 STUDY APPROACH AND STUDY TASKS

2.1 Study Goals and Objectives

This study aims to establish the total costs of ownership for selected water heating technologies in California IOU territories. The selected water heating technologies include:

- a. Efficient gas tank water heater, 40 gallon
- b. Efficient gas instantaneous water heater
- c. Heat pump water heater, 50 gallon
- d. Efficient electric tank water heater
- e. Efficient electric tank water heater, grid interactive

Specifically, the CPUC seeks to understand the total cost of ownership of heat pump water heating systems and competing technologies for two customer groups:

- 1. Single family occupants
 - a. Standard residential electric and gas rate plans
 - b. TOU residential rate plan
 - c. Low income residential rate plan (this group includes those with no access to natural gas for water heating purposes, such as those in the San Joaquin Valley)

⁷ http://www.energy.ca.gov/2014publications/CEC-500-2014-108/CEC-500-2014-108.pdf

⁸ http://www.brattle.com/news-and-knowledge/news/report-by-brattle-economists-finds-electric-water-heaters-can-provide-economic-andenvironmental-benefits

- 2. Multifamily building occupants and owners
 - a. Standard residential electric and gas rate plans
 - b. TOU residential rate plan
 - c. Low income residential rate plan

The multifamily portion of the study aims to determine if heat pump water heaters are an attractive opportunity for owners to make upgrades to their buildings without unforeseen CAZ mitigation costs.

This study also includes a back-of the-envelope style economic analysis to determine if grid-connected efficient electric storage water heater installations could be an opportunity improve the reliability and lower the environmental footprint of California's grid while providing an economic benefit as well.

The primary objectives of this study are as follows:

- 1. Determine the net present value (NPV) of the total cost of ownership of the above customer and water heating technology combinations.
- 2. Determine total CO₂ emissions for each of the customer and water heating technology combinations described above.
- 3. Compare the options on total cost of ownership and CO₂ emissions.
- 4. Provide insight on the results in the context of California's future (i.e. all net-zero buildings, increased penetration of renewables)

DNV GL also intends to:

- In the context of AB 2672, provide basis to help the commission determine whether heat pump water heaters are a cost effective option for single family homes in disadvantaged communities.
- Determine if heat pump water heaters are a cost-effective replacement for gas water heaters in multi-family buildings.
- Determine if grid-enabled water heaters are a cost effective option for both single family homes in disadvantaged communities and multifamily owners and occupants.

2.2 Study approach

Specifically, we will consider the two different customer segments for this study and three water heating technologies. The customers and water heating technology combinations are as follows:

- 1) Residential single family, replacing standard 40 gallon electric water heater. Potential replacement options include:
 - a. Efficient gas tank water heater, 40 gallon (extension of natural gas line not included)
 - b. Efficient gas instantaneous water heater (extension of natural gas line not included)
 - c. Heat pump water heater, 50 gallon
 - d. Efficient electric tank water heater, 40 gallon
 - e. Efficient electric tank water heater, 40 gallon, grid interactive

- 2) Multi-family building owner who needs to replace 5 or more standard 40 gallon gas water heatersone per residence. Potential replacement options include:
 - a. Efficient gas tank water heater, 40 gallon (extension of natural gas line not included)
 - b. Heat pump water heater, 50 gallon
 - c. Efficient electric tank water heater, 40 gallon
 - d. Efficient electric tank water heater, 40 gallon, grid interactive

For each customer and each water heating technology option we will attempt to determine the total cost of ownership including upfront costs, standard installation costs, as well as other costs such as Combustion Appliance Zone (CAZ) testing and mitigation, and non-standard installation costs, like installing condensate drains for a heat pump water heater. We will consider a number of factors that can have an impact on the overall cost of ownership including climate, utility rates, and feasibility of installation. We will also explore technical and regulatory barriers that exist for each option.

DNV GL will use life-cycle cost analysis (LCCA) over a 10-year period and assume each of the technologies has at least a 10-year lifetime. Table 1 gives key cost estimates for each of the customer and technology combinations.

Technology to be replaced:	Technology to be installed:	Key cost estimates			
	Efficient gas water heater, tank and instantaneous	Purchase price Installation costs CAZ testing CAZ mitigation costs Local natural gas line extension Gas prices			
\Single Family Electric water heater	Electric heat pump water heater	Purchase price Installation costs Drain installation Electric rates Estimated performance for CA climate zone			
	Efficient electric water heater, standard and grid interactive	Purchase price Installation costs Electric rates Grid connectivity Estimated ancillary benefit			
	Efficient gas water heater	Purchase price Installation costs CAZ testing CAZ mitigation costs Gas rates			
Multi-family single-unit gas water heater	Electric heat pump water heater	Purchase price Installation costs Drain installation Local electrical extension Estimated performance for CA climate zone			
	Efficient electric water heater, standard and grid interactive	Purchase price Installation costs			

Table 1: Key cost estimates for each water heating technology and customer combinations Technology to be replaced; Technology to be installed;

Local electrical extension Grid connectivity Estimated ancillary benefit

Key data resources include, IOU tracking databases for purchase price and installation costs and primary data collected during interviews with market actors.

2.3 Study Tasks

2.3.1 Task 1: Data gathering, Tracking Database, Literature review

Objective: The goal of this task is to review material to determine what information is available and to develop a list of characteristics to draw from IOUs databases. Outcomes from this task will include; documenting potential sources of data inputs such as costs; and determining sources for costs and other required data.

This activity includes investigating total project costs for multifamily and single family heat pump and competing technologies. Possible sources include utility databases, primary data collection, and other literature. As necessary, we will request input from water heater installers, CAZ testers, and other experts in the field. We will talk to current multi-family and other program staff to gain further insight on the costs and benefits of switching to an electric-based water heating system.

We will research the most-current information on grid-interactive water heaters and results of pilots in the field, and total costs.

Key documents we either have reviewed or will review include:

- CLASS database
- CEC EPIC funded water heating studies
- EPRI heat pump water heater studies
- Brattle group study
- Life Cycle costs best practices
- Energy Star Water Heater Market Profile
- NYSERDA Domestic Water Heater Performance for NY Homes
- DEER and supporting CA work papers
- PG&E's Emerging Technologies Program: Market-Focused Program Design to Accelerate Penetration of ENERGY STAR Water Heaters

2.3.2 Task 2: Research Plan

Objective: Document study approach, scope of work, schedule and project communications.

This document meets the draft deliverable for this Task. We will finalize the Research Plan based on feedback from the ED Project Manager, the IOUs, stakeholders, and public commenters (as appropriate).

Deliverables:

• Final Research Plan for California Residential Water Heating Technology Assessment

2.3.3 Task 3: Interviews and Data Collection

Objective: Determine values for key cost estimates

This task includes developing data requests, decipher and review data request materials, develop data collection methodology, conduct primary data collection interviews on data not accessible from IOUs.

Depending on available data sources, it may be necessary to collect primary data in the form of interviews. As listed above, possible interview subjects include water heater installers, CAZ testers, multi-family building owners, utility program staff, ED staff, and experts in the water heating field. Potential interview topics include cost of typical projects, cost of typical CAZ testing, rate of CAZ testing failures, typical mitigation requirements and associated costs, decision making process of energy upgrades, and program goals. We estimate we will complete 10 interviews. DNV GL will draft interview guides, solicit ED feedback, and complete interviews.

Deliverables:

- Data Requests
- Interview guides
- Interview target summary

2.3.4 Task 4: Research and Analysis

Objective: The purpose of this task will be to develop lifecycle cost models, determine costs and model inputs, and determine cost of ownership for each of pre-determined water heater use case.

DNV GL will use a spreadsheet based life-cycle cost analysis (LCCA) to determine the most cost effective option among the competing technologies for each of the following use cases:

- 1) Residential single family, replacing standard 40 gallon electric water heater. Potential replacement options include:
 - a. Efficient gas tank water heater, 40 gallon (extension of natural gas line not included)
 - b. Efficient gas instantaneous water heater (extension of natural gas line not included)
 - c. Heat pump water heater, 50 gallon
 - d. Efficient electric tank water heater, 40 gallon
 - e. Efficient electric tank water heater, 40 gallon, grid interactive
- 2) Multi-family building owner who needs to replace 5 or more standard 40 gallon gas water heaters in his residence. Potential replacement options include:
 - a. Efficient gas tank water heater, 40 gallon (extension of natural gas line not included)
 - b. Heat pump water heater, 50 gallon
 - c. Efficient electric tank water heater, 40 gallon
 - d. Efficient electric tank water heater, 40 gallon, grid interactive

Lifecycle costs include costs to purchase, install, maintain, and dispose of water heaters. DNV GL will also estimate the revenue generated by water heaters in the case of the grid interactive water heaters.

Environmental costs will not be included; however, DNV GL will also estimate the total CO2 impact of each of the scenarios.

The study team will estimate the following costs:

• First costs

٠

- Cost to install
 - Including additional plumbing and/or electrical work for any fuel switching
 - Cost associated with Combustion Appliance Zone testing
 - Cost to complete test
 - Cost to mitigate any testing failures
- Operating costs
 - Cost of energy
 - Based on load curve
 - Additional operating costs
 - Grid connection costs, as applicable
 - Maintenance costs, as applicable

Each of the costs will be projected for a 10 year period, a present value (PV) will of the project cost will be calculated, and the costs will be summed to determine the net present value (NPV) of each of the water heater technologies and customer combinations. Table 2 is shows an example of one such calculation.

				5	Ingle Fa	amily						
	COST OF	ELECT	RIC W	ATER	HEATE	R						
		Today	Year	Year	Year	Year	Year	Year	Year	Year	Year	Year
			1	2	3	4	5	6	7	8	9	10
First Cost		\$1,000										
Operating Cost			\$519	\$535	\$551	\$567	\$584	\$602	\$620	\$638	\$657	\$677
Subtotal		\$1,000	\$519	\$535	\$ 551	\$567	\$584	\$602	\$620	\$638	\$657	\$ 677
PV		\$1,000	\$494	\$485	\$ 476	\$467	\$458	\$449	\$440	\$ 432	\$ 424	\$ 416
NPV	\$ 5,540											

Table 2: Example NPV calculation

To estimate costs, the study team will use California-based previously estimated costs where available, such as those included in work papers available in the Database for Energy Efficient Resources (DEER). The study team will also use average costs from water heating tracking data, where applicable. When these data sources fail, the study team will use in-depth interviews with contractors and/or obtain representative bids to develop original costs estimated. As necessary, we will request input from water heater installers, CAZ testers, and other experts in the field. We will talk to current multi-family and other program staff to gain further insight on the costs and benefits of switching to an electric-based water heating system. We will research the most-current information on grid-interactive water heaters and results of pilots in the field, and total costs.

Deliverables:

• Develop sample frame based on available data on contacts for: water heater installers, water heater program participants, water heater experts, CAZ and HERs raters, multi-family building owners.

2.3.5 Task 5: Report on Findings

Objective: Deliver final report that summarizes the results of the water heating economic assessment.

At the conclusion of the data collection, research, and analysis, DNV GL will prepare a draft report summarizing the results from the above tasks. We will finalize the research report based on feedback from the ED Project Manager, the IOUs, stakeholders, and public commenters (as appropriate).

Deliverables:

- Draft report
- Public webinar
- Response to comments
- Final report

2.3.6 Task 6: Project Management

DNV GL will provide day-to-day management for all project activities including managing schedules, invoicing, staffing needs, etc. DNV GL will maintain regular contact with the project team via monthly meetings (can be more often if needed) and progress reports.

Deliverables:

- Monthly invoices
- Bi-weekly check-in meetings and progress reports

2.3.7 Project Timeline

DNV GL will initiate project within 2 weeks after team approval. Timeline is driven by availability of subjects for interviews. Table 3 displays the proposed project timeline and budget.

Table 3: Project Timeline and Budget

ABOUT DNV GL

Driven by our purpose of safeguarding life, property and the environment, DNV GL enables organizations to advance the safety and sustainability of their business. We provide classification and technical assurance along with software and independent expert advisory services to the maritime, oil and gas, and energy industries. We also provide certification services to customers across a wide range of industries. Operating in more than 100 countries, our 16,000 professionals are dedicated to helping our customers make the world safer, smarter and greener.

				This study proposal is not really studying technologies. It is really more of a cost benefit case study given a specific water heating implementation options for certain population (i.e., lower income) or geographic location (i.e.) koke (a access to cas). While it is geod to conduct some cases analyses; with limited generalization to look at economic cas-back of certain implementations. For the technology and market	We will update to include adding electric water heaters.
1	1	SCE	1	location (i.e., new access to ga), while it is good to conduct some cases analyses (with initiate generalization) to now a contraining particular by product or certain imperiation scenarios. For the technology and initiate characterization, it would be beneficial to provide a broader characterization of the overall water heating options for residential customers. This analysis should take a comprehensive evides of at all available	
				water heating options including standalone resistance water heating options that is not grid-enabled as well as grid-enabled options.	
2	1	SCE	1	For the cost benefit economic analysis, since the study will be more like a case analysis, why not make it more target-population specific.	It is target population specific. It's Multifamily units with 5+ individual units, and communities with electric
3	1	SCE	1	The water heating choices and time-of-use may be increasingly important as California moves forward to dynamic rate implementation. This economic analysis should not be static. It makes sense to present the	We agree and have planned to provide scenario analysis. Electric/gas rates, and load shapes
				findings as scenario analysis give the variables under evaluation (i.e., usage behavior, purchase behavior, electivic/gas rate scenario, etc.) Also, we need to make it clear that this study is aimed to look at implementation and adoption scenario for 1.2 years or 3 4 or 5 or beyond years. The answers from this study, timing and applicability may vary. It	This study is looking at current costs and options available on the market.
4	1	SCE	1	has we need to more reaching a source source and a source	This study is looking at current costs and options available on the market.
5	2	SCE	2	Let's make this more explicit. Can we say that this is ESAP qualified communities? By making this clear, we can focus our research in the 80% income qualified geographic locations. Otherwise, you will need to	This study is not ESAP-exclusive. We are assessing economic impact under 3 rates: Standard, Standard To
5	2	SUE	2	carefully breakdown the various responses by different demographic and income levels.	and Standard Low-Income
6	3	SCF	3	In the multi-family apartment, there may be two scenarios for water heating: (1) central water heating for the whole apartment is the typical arrangement for smaller apartments (i.e., 8-12 units), (2) individual	For this study we are only considering building under number (2) in your comment; units with individual w heaters.
0	3	SUE	3	apartment water heater for others (i.e., multi-family condo, where the ownership of the asset resides with the condo owners). The analysis may vary based on the ownership arrangement and apartment size. Let's make surve ware addressing specific scenario reinter than over-generalizing the results but specific answers are needed.	neaters.
7	4	0.05		Why does the water heater need to be grid-enabled? Perhaps, we need to look at grid-independent and grid-enable as two different options. We can leave it to the homeowners to decide.	Grid-enabled water heaters are revenue generating. We will consider the economics of both standard
7	4	SCE	3		storage water heaters and grid-enabled heaters
8	5	SCE	3	We should look at the full range of NPV for grid-independent and grid-enable technologies and options. We should look at gas vs electric powered units separately.	We will consider electric storage, electric HPWH, electirc storage-grid enabled, and gas storage water
-					heaters. They will all be compared to one another on economics and emissions This does not describe simple resistance heating. This describes solar water heating. Solar water heating
9	5	SCE	3	We should also look at simple resistance heating (i.e., run water through black coil during day time to get heating) as a low-tech and low-cost option? This may be used a hot water heating option for the summer- month. In this notion, you may have grid-enable and grid-independent water heating options side-by-side. The homeowners can make a decision on which one to select and pay for their choice.	out of scope of this study.
10	5	SCE	3	We also need to consider the tankless water heaters. Many households have switched over to tankless water heating to get ride of the water tank.	We will add tankless water heaters
11	5	SCE	3	I recommend we identify the full range of options, then decide on which one to focus. Otherwise, this study may look not balance and incomplete.	We will consider electric storage, electric HPWH, electirc storage-grid enabled, gas tankless, and gas store
**	, , , , , , , , , , , , , , , , , , ,	JUL	5		water heaters. They will all be compared to one another on economics and emissions
12	6	SCE	3	You should consider labeling this as a case study, since you are narrowing your view to specific cases and situations.	We will consider the economics under 3 rates: Standard, Standard TOU, and Standard Low-Income; Thus, they are not case studies, these situations cover numerous customers.
13	7	SCE	4	Since electricity and gas rates and costs may be very dynamic, especially in light of upcoming dynamic rate implementation in California.	they are not case studies, these situations cover numerous customers. We will set up the model so the rates can chage.
14	7	SCE	4	This analysis should not be static. You should show a range of NPV situation, give notifierent rate and usage assumptions.	We agree; this is what we are planning on doing.
15	1	PG&E	1	Does this take into account new 2015 Federal Code for units over 55 gallons that mandates HP technology for electric WHs and condensing technology for gas storage WHs?	No, we are considering only 40 gallon water heaters
16	2	PG&E	2	Will this focus on central systems or individual in-unit equipment intended to serve single apartments?	This study will focus on MF with individual in-unit equipment intended to serve single apartments.
17	3	PG&E	3	Again, need to distinguish between central vs. in-unit configurations for MF buildings. This seems to point at the study only reviewing in-unit WH equipment, however many CA MF properties use central systems and we may want to also review these scenarios within the study.	This study will focus on MF with individual in-unit equipment intended to serve single apartments. This study will focus on MF with individual in-unit equipment intended to serve single apartments. The size
18	4	PG&E	3	In seems to point at the study only reviewing in-unit will equipment, nowever many CA ME properties use central systems and we may want to also review these scenarios within the study.	I his study will focus on MF with individual in-unit equipment intended to serve single apartments. The siz and situation of larger systems is too varied to include.
19	5	PG&E	4	This should not only account for upcoming TOU rate requirements, but also the possibility that a customer does/doesn't have solar PV.	The study will include current TOU rates.
20	1	SCG	3	Recommend adding (d) tankless water heater as an option. Also, recommend adding option (d) tankless water heater.	We will add tankless water heaters
21	2	SCG	3	In the below chart this says gas – assuming this should be gas.	Will correct

The study should include the electric heating tarff and the EV-charging TOU tarff. The liminary analysis suggests that bot the current TOU tarks and and they alter enough baseline to make electric heating economical as households get bumped into higher tiers. Tariffs that incentrive heating in dfreek periods (with a large peak and off-peak	Agreeed, but this research is out of scope of our study. The Brattle study considered this options, please st http://www.rneca.coop/wp.content/uploads/2016/02/The-Hidden-Battery-01-25-2016.pdf This study will consider the three rates as described to lay ground work that could include additional rate structures. Will recommend as a topic for future study. The EFs for the water heaters in this study will meet MEPS for California. Will recommend higher efficienc water heaters are evaluated in future studies. Heat pump water heaters perform better in warmer climates. This study will use DEER average values for unit energy consumption. Regional differences in performance are out of scope. This study ounsiders interactive effects. This study will use DEER average values for the unit energy consumption. Interactive effects are out of scope. This study considers cost from the customer point of view. Will recommend that future study consider the cost of providing gas infastructure. This study considers cost from the customer point of view. Will recommend that future study consider the cost of providing gas infastructure.
29 30 31 32 33 34 35 36	1 2 2 3 3 3 3	Rachel Golden Rachel Golden Rachel Golden Rachel Golden Rachel Golden Rachel Golden Rachel Golden	°	The term "Solar plus Storage" will become widespread incorporating the heavy deployment of Grid-Interactive Water Isader Heaters (GIWH) – some of which can duplicate nearly all the fast-ramp gridservices as batteries. As Distributive Energy Resources (DER's) become monetized (and revended) portions of that revenue will flow directly to purchasers of GIWH and Solar plus GIWH Systems – greatly influencing the Present Value calculations. Consideration in the final days of research should also involve larger "Grid Enabled" ERWH as these tanks better handle the volatility of day-to-day end-user hot water usage (similar to The proposed study covers a very important scope of analysis and a current research gap. Our questions and comments seek to ensure the results of the study inform decision-making around a broad trange regulatory and utility strategies to achieve EE and climate gaals in CA. 1) The study only looks at the economics of fuel-shwiching for multi-family homes. Is usolid also include the electric time Will and the schedule and loss grid interactive the economics of fuel-shwiching for multi-family homes though may be good 2). The study should include 60 galoni HPWHs incluing 15 G galion) and also grid interactive HPWHs (not just grid-interactive similar to electric tank water heaters. This 3) In order to inform what rate structures are needed for lectric water heating. To the consumer, the study should include de conomic analysis of a broader variety of traffs. The study should include the electric heating tarff and the EV-charging TOU tarff. Felliminary analysis suggests that bot the current TOU tares and standard but the electric in kWHs and level to thave a large enough baseline to make electric heating economical as households get bumped into higher tiers. Tarffs that incentive heating in off-peak periods (with a large peak and off-peak rate differential) and with adequate allowance for heating may be needed. Analysis of a larger varied of the structure sociul inform most rate electry in kwest	Agreeed, but this research is out of scope of our study.
